

Package ‘genomeIntervals’

April 5, 2014

Version 1.18.0

Date 2013-03-13

Type Package

Title Operations on genomic intervals

Author Julien Gagneur <gagneur@genzentrum.lmu.de>, Joern Toedling, Richard Bourgon, Nicolas Delhomme

Maintainer Julien Gagneur <gagneur@genzentrum.lmu.de>

Depends R (>= 2.15.0), methods, intervals (>= 0.14.0), BiocGenerics (>= 0.3.2)

Imports methods, Biobase

Suggests

Description This package defines classes for representing genomic intervals and provides functions and methods for working with these.

Note: The package provides the basic infrastructure for and is enhanced by the package 'girafe'.

License Artistic-2.0

[intervals](#)

c

Combine genome intervals objects

Description

S3 methods for combining several genome intervals into a single one.

Usage

```
## S3 method for class Genome_intervals  
c(...)  
## S3 method for class Genome_intervals_stranded  
c(...)
```

Arguments

... [Genome_intervals](#) or [Genome_intervals_stranded](#) objects.

Details

If the arguments have mixed classes (both [Genome_intervals](#) or [Genome_intervals_stranded](#)), then they are coerced to [Genome_intervals](#) before combination. Otherwise, the common class is used.

Value

A single [Genome_intervals](#) or [Genome_intervals_stranded](#) object. Input objects are combined in their order of appearance in the the argument list.

If any input argument is not a [Genome_intervals](#), `list(...)` is returned instead.

Note

These methods will be converted to S4 once the necessary dispatch on . . . is supported.

Examples

```
# load toy examples
data("gen_ints")

# combine i and j returns a Genome_intervals_stranded object
c( i, j )

# combine a not-stranded and a stranded returns a not-stranded object
c( as(i, "Genome_intervals"), j )
```

core_annotated	<i>Genome intervals with minimal annotation</i>
----------------	---

Description

returns a copy of the input (stranded) genome intervals object with annotations restricted to the minimally required ones.

Usage

```
core_annotated(x)
```

Arguments

x A [Genome_intervals](#) or [Genome_intervals_stranded](#) object.

Value

A copy of x with the annotation slot restricted to seq_name, inter_base and strand (the latter only if x is a [Genome_intervals_stranded](#) object).

Examples

```
# load toy examples
data("gen_ints")

# add some non-core annotations to i
annotation(i)$comment = "some non-core annotation"

# i with all annotations
i

# core annotations only
core_annotated(i)
```

```
## Not run:  
# with different annotation columns, i and j cannot be combined  
c( i, j )  
  
## End(Not run)  
  
# core annotated versions can  
c( core_annotated(i), core_annotated(j) )
```

distance_to_nearest *Distance in bases to the closest interval(s)*

Description

Given two objects, `from` and `to`, compute the distance in bases of each from interval to the nearest to interval(s). The distance between a base and the next inter-bases on either side values 0.5. Thus, base - base and inter-base - inter-base intervals distances are integer, whereas base - inter-base intervals distances are half-integers.

Usage

```
## S4 method for signature Genome_intervals,Genome_intervals  
distance_to_nearest(from, to)  
## S4 method for signature Genome_intervals_stranded,Genome_intervals_stranded  
distance_to_nearest(from, to)
```

Arguments

`from` A [Genome_intervals](#) or [Genome_intervals_stranded](#) object.
`to` A [Genome_intervals](#) or [Genome_intervals](#) object.

Details

A wrapper calling [intervals::distance_to_nearest](#) by `seq_name` and by `strand` (if both `from` and `to` are [Genome_intervals_stranded](#) objects). Thus, if both are stranded, distances are computed over each strand separately. One object must be coerced to [Genome_intervals](#) if this is not wished.

Value

A numeric vector of distances with one element for each row of `from`.

See Also

[intervals::distance_to_nearest](#)

Examples

```

## load toy examples
data(gen_ints)

## i in close_intervals notation
close_intervals(i)

## j in close_intervals notation
close_intervals(j)

## distances from i to j
dn = distance_to_nearest(i,j)
dn

## distance == 0 if and only if the interval overlaps another one:
io = interval_overlap(i,j)
if( any( ( sapply(io, length) >0 ) != (!is.na(dn) & dn ==0) ) )
  stop("The property distance == 0 if and only if the interval overlaps another one is not followed for at least one i")

## distances without strand-specificity
distance_to_nearest(
  as(i,"Genome_intervals"),
  as(j,"Genome_intervals")
)

```

GenomeIntervals

Constructor function for genomeIntervals objects

Description

A user-friendly constructor function for creating both `Genome_intervals` and `Genome_intervals_stranded` objects.

Usage

```

GenomeIntervals(chromosome, start, end, strand = NULL,
  inter.base = NULL, leftOpen = NULL,
  rightOpen = NULL, ...)

```

Arguments

chromosome	character vector of chromosome names of the intervals; will become the <code>seq_names</code> of the resulting object
start	numeric or integer; start (left-most) coordinate of the intervals
end	numeric or integer; end (right-most) coordinate of the intervals
strand	character; specifies which strand the intervals are located on; if specified an object of class <code>Genome_intervals_stranded</code> is created; if <code>NULL</code> an object of class <code>Genome_intervals</code> is created

<code>inter.base</code>	logical; if TRUE an interval is located between the specified coordinates, instead of spanning them; useful for restriction-enzym cutting sites, for example.
<code>leftOpen</code>	logical; if TRUE an interval is left-open; if NULL all intervals are assumed to be left-closed.
<code>rightOpen</code>	logical; if TRUE an interval is right-open; if NULL all intervals are assumed to be right-closed.
<code>...</code>	any additional annotation for supplied intervals

Details

The arguments `chromosome`, `start`, and `end` need to be of the same length, with the first element of each vector corresponding to the first interval, the second element to the second interval, and so on.

The same applies to `strand`, `inter.base`, `leftOpen`, `rightOpen` and any additional vectors in `'...'`, if they are specified.

Value

An object of class `Genome_intervals` or `Genome_intervals_stranded` depending on whether `strand` has been specified.

  strand=c("-", "-", "+", "+", "+", "+"),
  GC.content=round(runif(6), digits=2))

show(GS)
```

 Genome_intervals-class

Class "Genome\intervals"

Description

A set of genomic intervals without specified strand. Genomic intervals are intervals over the integers with two further annotations: `seq_name` (a chromosome or more generally a sequence of origin) and `inter_base` (logical) that states whether the interval is to be understood as an interval over bases (such as coding-sequence) or inter-bases (such as restriction sites or insertion positions).

Slots

`.Data`: See [Intervals_full](#)

`annotation`: A "data.frame" with the same number of rows as `.Data`. It has a column named `seq_name` that is a factor and does not contain missing values. `seq_name` is used to represent the chromosome or more generally the sequence of origin of the intervals. `annotation` has a column named `inter_base` that is logical and does not contain missing values. `inter_base` is FALSE if the interval is to be understood as an interval over bases (such as coding-sequence) and TRUE if it is over inter-bases (such as restriction site or an insertion position). Like base intervals, inter-base interval are encoded over the integers. An inter-base at position `n` indicates the space between base `n` and `n+1`.

`closed`: See [Intervals_full](#)

`type`: See [Intervals_full](#)

Extends

Class "[Intervals_full](#)", directly. Class "[Intervals_virtual](#)", by class "Intervals\full", distance 2. Class "[matrix](#)", by class "Intervals\full", distance 3. Class "[array](#)", by class "Intervals\full", distance 4. Class "[structure](#)", by class "Intervals\full", distance 5. Class "[vector](#)", by class "Intervals\full", distance 6, with explicit coerce.

Methods

```
[ signature(x = "Genome_intervals"): ...
[[ signature(x = "Genome_intervals"): ...
[<- signature(x = "Genome_intervals"): ...
\<- signature(x = "Genome_intervals"): ...
\<- signature(x = "Genome_intervals"): ...
annotation signature(object = "Genome_intervals"): ...
annotation<- signature(object = "Genome_intervals"): ...
coerce signature(from = "Genome_intervals", to = "Intervals_full"): ...
coerce signature(from = "Genome_intervals", to = "character"): ...
```

```

coerce signature(from = "Genome_intervals", to = "data.frame"): ...
distance\to\nearest signature(from = "Genome_intervals", to = "Genome_intervals"):
  ...
inter\base signature(x = "Genome_intervals"): ...
inter\base<- signature(x = "Genome_intervals"): ...
interval\complement signature(x = "Genome_intervals"): ...
interval\intersection signature(x = "Genome_intervals"): ...
interval\overlap signature(from = "Genome_intervals", to = "Genome_intervals"): ...
interval\union signature(x = "Genome_intervals"): ...
seq\name signature(x = "Genome_intervals"): ...
seq\name<- signature(x = "Genome_intervals"): ...
size signature(x = "Genome_intervals"): ...
type<- signature(x = "Genome_intervals"): ...
which\nearest For each interval in Set1, finds nearest (least distant) interval in Set2. Intervals
  on different chromosomes are never considered 'near' to each other. The returned value is a
  data.frame with the number of rows equal to the number of intervals in Set1. Each row
  specifies the distance to the nearest interval in Set2 (a 0 means that the interval overlaps one
  or more intervals in Set2), and the indices of near and overlapping intervals in Set2. See
  Intervals\_full for further details.

```

Note

A Genome_intervals is a "[Intervals_full](#)" of type Z (i.e. a set of intervals over the integers). The annotation slot can carry further columns that can serve as annotations.

See Also

[Genome_intervals_stranded](#) for a derived class that allows stranded genomic intervals.

Examples

```

# The "Genome_intervals" class

i <- new(
  "Genome_intervals",
  matrix(
    c(1,2,
      3,5,
      4,6,
      8,9
    ),
    byrow = TRUE,
      ncol = 2
  ),
  closed = matrix(
    c(
      TRUE, FALSE,

```

```

TRUE, FALSE,
TRUE, TRUE,
TRUE, FALSE
),
byrow = TRUE,
  ncol = 2
),
annotation = data.frame(
  seq_name = factor(c("chr01", "chr01", "chr02", "chr02")),
  inter_base = c(FALSE, FALSE, TRUE, TRUE)
)
)

colnames(i) <- c( "start", "end" )

# print
print(i)

# size (number of bases per interval)
size(i)

## convert to a data.frame
as(i, "data.frame")

## simpler way to construct a Genome_intervals object:
G <- GenomeIntervals(start=c(1,3,4,5,10,8), end=c(5,5,6,8,11,9),
  chromosome=rep(c("chr2", "chrX", "chr1"), each=2),
  leftOpen=rep(c(FALSE, FALSE, TRUE), 2))

show(G)

```

Genome_intervals-ordering

Ordering methods for Genome intervals

Description

An order is defined on genome intervals and stranded genome intervals to allow `sort()`, `order()` and `rank()`.

Usage

```

## S4 method for signature Genome_intervals
order(..., na.last=TRUE, decreasing=FALSE)
## S4 method for signature Genome_intervals_stranded
order(..., na.last=TRUE, decreasing=FALSE)

## S4 method for signature Genome_intervals
sort(x, decreasing=FALSE, ...)

```

```
## S4 method for signature Genome_intervals
rank(x, na.last=TRUE,
      ties.method = c("average", "first", "random", "max", "min") )
## S4 method for signature Genome_intervals
xtfrm(x)
```

Arguments

<code>x</code>	Objects of class Genome_intervals or Genome_intervals_stranded .
<code>...</code>	Objects of class Genome_intervals , Genome_intervals_stranded or of any other class for order.
<code>na.last</code>	Ignored for ordering Genome_intervals and Genome_intervals_stranded objects
<code>decreasing</code>	TRUE or FALSE.
<code>ties.method</code>	A character string specifying how ties are treated. Only "first" is supported.

Details

An order on `Genome_intervals` entries is defined by sorting by 1. `seq_name` 2. `start`, where closed `start` & not `inter-base` < closed `start` & `inter-base` < open `start` & not `inter-base` < open `start` & `inter-base` 3. `stop`, where open `stop` & not `inter-base` < open `stop` & `inter-base` < closed `stop` & not `inter-base` < closed `stop` & `inter-base` 4. `strand` (for `Genome_intervals_stranded` object)

The factors `seq_name` and `strand` are sorted according to their levels (default R behavior).

The primitive is implemented in `xtfrm` which is then called by the other methods. Hence, the order, `sort` and `rank` methods are consistent.

`order(..., na.last=TRUE, decreasing=TRUE)`: return a permutation which rearranges its first argument into ascending or descending order, breaking ties by further arguments. See [order](#) in the base package for more details. `na.last` is ignored for [Genome_intervals](#) objects.

`rank(x, na.last=TRUE, ties.method=c("average", "first", "random", "max", "min"))`: Return the sample ranks of the (stranded) genome intervals in `x`. See [rank](#) in the base package for more details.

`sort(x)`: Sort `x`. See [sort](#) in the base package for more details.

`xtfrm(x)`: Auxiliary function that produces a numeric vector which will sort in the same order as 'x' `x`. See [xtfrm](#) in the base package for more details. Workhorse for the other methods

See Also

[Genome_intervals](#) [Genome_intervals_stranded](#) [order](#), [sort](#), [rank](#), [xtfrm](#)

Examples

```
## an example with ties
gi = GenomeIntervals(c("chr2", "chr2", "chr1", "chr1"), c(1,1,10,10), c(5,3,12,12) )
```

```

sort(gi)
rank(gi)
order(gi)

## Define order on seq_names at your convenience
## by specifying the order of the levels
## compare:
gi = GenomeIntervals(
  c("chr2", "chr2", "chr10", "chr10"),
  c(1,1,10,10),
  c(5,3,12,12)
)
sort(gi)

## with:
gi2 = GenomeIntervals(
  factor(c("chr2", "chr2", "chr10", "chr10"), levels=c("chr2", "chr10")),
  c(1,1,10,10),
  c(5,3,12,12)
)
sort(gi2)

```

Genome_intervals_stranded-class

Class "Genome\intervals\stranded"

Description

A set of genomic intervals with a specified strand.

Slots

.Data: See [Genome_intervals](#)

annotation: A data.frame (see [Genome_intervals](#) for basic requirements). The annotation moreover has a strand column that is a factor with exactly two levels (typically "+" and "-").

closed: See [Genome_intervals](#)

type: See [Genome_intervals](#)

Extends

Class "[Genome_intervals](#)", directly. Class "[Intervals_full](#)", by class "Genome\intervals", distance 2. Class "[Intervals_virtual](#)", by class "Genome\intervals", distance 3. Class "[matrix](#)", by class "Genome\intervals", distance 4. Class "[array](#)", by class "Genome\intervals", distance 5. Class "[structure](#)", by class "Genome\intervals", distance 6. Class "[vector](#)", by class "Genome\intervals", distance 7, with explicit coerce.

Methods

```

coerce signature(from = "Genome_intervals_stranded", to = "character"): ...
distance\to\nearest signature(from = "Genome_intervals_stranded", to = "Genome_intervals_stranded"): ...
...
interval\complement signature(x = "Genome_intervals_stranded"): ...
interval\intersection signature(x = "Genome_intervals_stranded"): ...
interval\overlap signature(to = "Genome_intervals_stranded", from = "Genome_intervals_stranded"): ...
...
interval\union signature(x = "Genome_intervals_stranded"): ...
strand signature(x = "Genome_intervals_stranded"): ...
strand<- signature(x = "Genome_intervals_stranded"): ...

```

See Also

[Genome_intervals](#) the parent class without strand.

Examples

```

# The "Genome_intervals_stranded" class
j <- new(
  "Genome_intervals_stranded",
  matrix(
    c(1,2,
      3,5,
      4,6,
      8,9
    ),
    byrow = TRUE,
      ncol = 2
  ),
  closed = matrix(
    c(
      FALSE, FALSE,
      TRUE, FALSE,
      TRUE, TRUE,
      TRUE, FALSE
    ),
    byrow = TRUE,
      ncol = 2
  ),
  annotation = data.frame(
    seq_name = factor( c("chr01","chr01", "chr02","chr02") ),
    strand = factor( c("+", "+", "+", "-") ),
    inter_base = c(FALSE,FALSE,FALSE,TRUE)
  )
)

## print

```

```

print(j)

## size of each interval as count of included bases
size(j)

## close intervals left and right (canonical representation)
close_intervals(j)

## simpler way to construct a Genome_intervals_stranded object
GS <- GenomeIntervals(start=c(1,3,4,5,8,10), end=c(5,5,6,8,9,11),
                      chromosome=rep(c("chr2", "chrX", "chr1"), each=2),
                      strand=c("-", "-", "+", "+", "+", "+") )

show(GS)

```

gen_ints

Genome Intervals examples

Description

Toy examples for testing functions and running examples of the package genomeIntervals.

Usage

```
data(gen_ints)
```

Format

Two Genome_intervals_stranded objects, i and j, without inter-base intervals and a third one, k, with.

getGffAttribute

Pull one or more key/value pairs from gffAttributes strings

Description

GFF files contain a string, with key/value pairs separated by “;”, and the key and value separated by “=”. This function quickly extracts one or more key/value pairs.

Usage

```
getGffAttribute(gi, attribute)
```

Arguments

gi A [Genome_intervals](#) object.
attribute A vector of key names.

Value

A matrix with the same number of rows as `gi`, and one column per element of attribute.

See Also

See [parseGffAttributes](#) for more complete parsing. See the function [readGff3](#) for loading a GFF file.

Examples

```
# Get file path
libPath <- installed.packages()["genomeIntervals", "LibPath"]
filePath <- file.path(
  libPath,
  "genomeIntervals",
  "example_files"
)

# Load gff
gff <- readGff3( file.path( filePath, "sgd_simple.gff"), isRightOpen=FALSE)

## head of full gff annotations
head(annotation(gff))

# extract ID and Parent attributes
idpa = getGffAttribute( gff, c( "ID", "Parent" ) )

head(idpa)
```

interval_overlap	<i>Assess overlap from one set of genomic intervals to another</i>
------------------	--

Description

Given two objects, a 'from' and a 'to', assess which intervals in 'to' overlap which of 'from'.

Usage

```
## S4 method for signature Genome_intervals,Genome_intervals
interval_overlap(
  from, to,
  check_valid = TRUE
)

## S4 method for signature Genome_intervals_stranded,Genome_intervals_stranded
interval_overlap(
  from, to,
```

```

        check_valid = TRUE
    )

```

Arguments

from A `Genome_intervals` or `Genome_intervals_stranded` object.
to A `Genome_intervals` or `Genome_intervals_stranded` object.
check_valid Should `validObject` be called before passing to compiled code?

Details

A wrapper calling `intervals:interval_overlap` by `seq_name` and by `strand` (if both `to` and `from` are `"Genome_intervals_stranded"` objects).

Value

A list, with one element for each row of `from`. The elements are vectors of indices, indicating which `to` rows overlap each `from`. A list element of length 0 indicates a `from` with no overlapping `to` intervals.

Examples

```

data(gen_ints)
# i as entered
i

# i in close_intervals notation
close_intervals(i)

# j in close_intervals notation
close_intervals(j)

# list of intervals of j overlapping intervals of i
interval_overlap(i,j)

```

interval_union

Genome interval set operations

Description

Compute interval set operations on `"Genome_intervals"` or `"Genome_intervals_stranded"` objects.

Usage

```
## S4 method for signature Genome_intervals
interval_union(x, ...)
## S4 method for signature Genome_intervals_stranded
interval_union(x, ...)

## S4 method for signature Genome_intervals
interval_complement(x)
## S4 method for signature Genome_intervals_stranded
interval_complement(x)

## S4 method for signature Genome_intervals
interval_intersection(x,...)
## S4 method for signature Genome_intervals_stranded
interval_intersection(x,...)
```

Arguments

x A "Genome_intervals" or "Genome_intervals_stranded" object.
... Optionally, additional objects of the same class as x.

Details

Wrappers calling the corresponding functions of the package `intervals` by same `seq_name`, `inter_base` and if needed `strand`. Note that the union of single input object `x` returns the reduced form of `x`, i.e. the interval representation of the covered set.

Value

A single object of appropriate class, representing the union, complement or intersection of intervals computed over entries with same `seq_name`, `inter_base` and also `strand` if all passed objects are of the class "Genome_intervals_stranded".

See Also

[interval_union](#), [interval_complement](#), [interval_intersection](#) and [reduce](#) from the package `intervals`.

Examples

```
## load toy examples
data(gen_ints)
## content of i object
i

## complement
interval_complement(i)

## reduced form (non-overlapping interval representation of the covered set)
interval_union(i)
```

```
## union
interval_union(i[1:2,], i[1:4,])

# map to genome intervals and union again
i.nostrand = as(i,"Genome_intervals")
interval_union(i.nostrand)

## intersection with a second object
# print i and j in closed interval notation
close_intervals(i)
close_intervals(j)

# interval_intersection
interval_intersection(i,j)

#interval intersection non-stranded
interval_intersection(i.nostrand, as(j, "Genome_intervals"))
```

parseGffAttributes *Parse out the gffAttributes column of a Genome\intervals object*

Description

GFF files contain a string, with key/value pairs separated by “;”, and the key and value separated by “=”. This function parses such strings into a list of vectors with named elements.

Usage

```
parseGffAttributes(gi)
```

Arguments

gi A [Genome_intervals](#) object.

Value

A list, with one element per row of gi. Each element is a character vector with named components. Names correspond to keys, and components correspond to values.

Note

Key/value pairs which are missing the “=” symbol, or which have nothing between it and the “;” delimiter or end of line, will generate a NA value, with a warning. Any key/value “pairs” with more than one “=” cause an error.

See Also

In many cases, [getGffAttribute](#), in this package, is easier and faster. See the function [readGff3](#) for loading a GFF file.

Examples

```
# Get file path
libPath <- installed.packages()["genomeIntervals", "LibPath"]
filePath <- file.path(
  libPath,
  "genomeIntervals",
  "example_files"
)

# Load gff and parse attributes
gff <- readGff3( file.path( filePath, "sgd_simple.gff"), isRightOpen = FALSE )
gfatt <- parseGffAttributes(gff)

head( gfatt )
```

readGff3	<i>Read (write) a Genome_intervals_stranded object from (to) a GFF3 file</i>
----------	--

Description

- readGff3 Make a [Genome_intervals_stranded](#) object from a gff file in gff3 format.
- writeGff3 Write a [Genome_intervals](#) object to a gff file in gff3 format.

Usage

```
readGff3(file, isRightOpen=TRUE)
writeGff3(object, file)
```

Arguments

file	The name of the gff file to read/write.
isRightOpen	Although a proper GFF3 file follows the convention of right-open intervals, improper GFF files following the right-closed convention are frequently found. Set <code>isRightOpen = FALSE</code> in this case.
object	a Genome_intervals object

Details

The file must follow gff3 format specifications as in <http://www.sequenceontology.org/gff3.shtml>. The file is read as a table. Meta-information (lines starting with `\#\#\#`) are not parsed. A “.” in, for example, the gff file’s *score* or *frame* field will be converted to NA. When the GFF file follows the right-open interval convention (`isRightOpen` is TRUE), then GFF entries for which end base equals first base are recognized as zero-length features and loaded as `inter_base` intervals. Strand entries in the file are expected to be ‘.’, ‘?’ , ‘+’ or ‘-’. The two first are mapped to NA. It can be that readGff3 is able to construct a [Genome_intervals_stranded](#) object from the input file, although not valid. A warning message is then generated and the constructed object is returned to allow inspection of it.

Value

A [Genome_intervals_stranded](#) object image of the gff file. The GFF3 fields seqid, source, type, score, strand, phase and attributes are stored in the annotation slot and renamed as seq_name, source, type, score, strand, phase and gffAttributes respectively.

Note

Potential FASTA entries at the end of the file are ignored.

See Also

The functions [getGffAttribute](#) and [parseGffAttributes](#) for parsing GFF attributes.

Examples

```
# Get file path
libPath <- installed.packages()["genomeIntervals", "LibPath"]
filePath <- file.path(
  libPath,
  "genomeIntervals",
  "example_files"
)

# Load SGD gff
# SGD does not comply to the GFF3 right-open interval convention
gff <- readGff3( file.path( filePath, "sgd_simple.gff"), isRightOpen = FALSE)

head(gff,10)

head(annotation(gff),10)

## write the gff3 file
## Not run:
writeGff3(gff,file="sgd_simple.gff")

## End(Not run)
```
