computeGeneSetsOverlap

Compute gene-sets overlap

Description

Calculates the overlap among every pair of gene-sets given as input.

Usage

```
## S4 method for signature 'list,character'  
computeGeneSetsOverlap(gSets, uniqGenes, min.sz=1, max.sz=Inf)  
## S4 method for signature 'list,ExpressionSet'  
computeGeneSetsOverlap(gSets, uniqGenes, min.sz=1, max.sz=Inf)  
## S4 method for signature 'GeneSetCollection,character'  
computeGeneSetsOverlap(gSets, uniqGenes, min.sz=1, max.sz=Inf)  
## S4 method for signature 'GeneSetCollection,ExpressionSet'  
computeGeneSetsOverlap(gSets, uniqGenes, min.sz=1, max.sz=Inf)
```

Arguments

<code>gSets</code>	Gene sets given either as a list or a <code>GeneSetCollection</code> object.
<code>uniqGenes</code>	Vector of unique genes to be considered when calculating the overlaps.
<code>min.sz</code>	Minimum size.
<code>max.sz</code>	Maximum size.

Details

This function calculates the overlap between every pair of gene sets of the input argument `gSets`. Before this calculation takes place, the gene sets in `gSets` are firstly filtered to discard genes that do not match to the identifiers in `uniqGenes`. Secondly, they are further filtered to meet the minimum and/or maximum size specified with the arguments `min.sz` and `max.sz`. The overlap between two gene sets is calculated as the number of common genes between the two gene sets divided by the smallest size of the two gene sets.

Value

A gene-set by gene-set matrix of the overlap among every pair of gene sets.

Examples

```
geneSets <- list(set1=as.character(1:4), set2=as.character(4:10))  
computeGeneSetsOverlap(geneSets, unique(unlist(geneSets)))
```

filterGeneSets *Filter gene sets*

Description

Filters gene sets through a given minimum and maximum set size.

Usage

```
## S4 method for signature 'list'  
filterGeneSets(gSets, min.sz=1, max.sz=Inf)  
## S4 method for signature 'GeneSetCollection'  
filterGeneSets(gSets, min.sz=1, max.sz=Inf)
```

Arguments

gSets	Gene sets given either as a list or a GeneSetCollection object.
min.sz	Minimum size.
max.sz	Maximum size.

Details

This function filters the input gene sets according to a given minimum and maximum set size.

Value

A collection of gene sets that meet the given minimum and maximum set size.

```

gsva

Gene Set Variation Analysis

Description

Estimates GSVA enrichment scores.

Usage

```
## S4 method for signature 'ExpressionSet,list'  
gsva(expr, gset.idx.list,  
      abs.ranking=FALSE,  
      min.sz=1,  
      max.sz=Inf,  
      no.bootstraps=0,  
      bootstrap.percent = .632,  
      parallel.sz=0,  
      parallel.type="SOCK",  
      verbose=TRUE,  
      mx.diff=TRUE)  
  
## S4 method for signature 'ExpressionSet,GeneSetCollection'  
gsva(expr, gset.idx.list,  
      abs.ranking=FALSE,  
      min.sz=1,  
      max.sz=Inf,  
      no.bootstraps=0,  
      bootstrap.percent = .632,  
      parallel.sz=0,  
      parallel.type="SOCK",  
      verbose=TRUE,  
      mx.diff=TRUE)  
  
## S4 method for signature 'matrix,list'  
gsva(expr, gset.idx.list,  
      abs.ranking=FALSE,  
      min.sz=1,  
      max.sz=Inf,
```

```

no.bootstraps=0,
bootstrap.percent = .632,
parallel.sz=0,
parallel.type="SOCK",
verbose=TRUE,
mx.diff=TRUE)

```

Arguments

<code>expr</code>	Gene expression data which can be given either as an <code>ExpressionSet</code> object or as a matrix of expression values where rows correspond to genes and columns correspond to samples.
<code>gset.idx.list</code>	Gene sets provided either as a <code>list</code> object or as a <code>GeneSetCollection</code> object.
<code>abs.ranking</code>	Flag to determine whether genes should be ranked according to their sign (<code>flag=FALSE</code>) or by absolute value (<code>flag=TRUE</code>). In the latter, pathways with genes enriched on either extreme (high or low) will be regarded as 'highly' activated.
<code>min.sz</code>	Minimum size of the resulting gene sets.
<code>max.sz</code>	Maximum size of the resulting gene sets.
<code>no.bootstraps</code>	Number of bootstrap iterations to perform.
<code>bootstrap.percent</code>	.632 is the ideal percent samples bootstrapped.
<code>parallel.sz</code>	Number of processors to use when doing the calculations in parallel. This requires to previously load either the <code>multicore</code> or the <code>snow</code> library. If <code>multicore</code> is loaded and this argument is left with its default value (<code>parallel.sz=0</code>) then it will use all available core processors unless we set this argument with a smaller number. If <code>snow</code> is loaded then we must set this argument to a positive integer number that specifies the number of processors to employ in the parallel calculation.
<code>parallel.type</code>	Type of cluster architecture when using <code>snow</code> .
<code>verbose</code>	Gives information about each calculation step. Default: <code>FALSE</code> .
<code>mx.diff</code>	Offers two approaches to calculate the enrichment statistic (ES) from the KS random walk statistic. <code>mx.diff=FALSE</code> : ES is calculated as the maximum distance of the random walk from 0. <code>mx.diff=TRUE</code> (default): ES is calculated as the magnitude difference between the largest positive and negative random walk deviations.

Details

GSVA assesses the relative enrichment of gene sets across samples using a non-parametric approach. Conceptually, GSVA transforms a p-gene by n-sample gene expression matrix into a g-geneset by n-sample pathway enrichment matrix. This facilitates many forms of statistical analysis in the 'space' of pathways rather than genes, providing a higher level of interpretability.

The `gsva()` function first maps the identifiers in the gene sets to the identifiers in the input expression data leading to a filtered collection of gene sets. This collection can be further filtered to require a minimum and/or maximum size of the gene sets for which we want to calculate GSVA enrichment scores, by using the arguments `min.sz` and `max.sz`.

Value

A gene-set by sample matrix of GSVA enrichment scores.

Examples

```
library(limma)

p <- 10 ## number of genes
n <- 30 ## number of samples
nGrp1 <- 15 ## number of samples in group 1
nGrp2 <- n - nGrp1 ## number of samples in group 2

## consider three disjoint gene sets
geneSets <- list(set1=paste("g", 1:3, sep=""),
                 set2=paste("g", 4:6, sep=""),
                 set3=paste("g", 7:10, sep=""))

## sample data from a normal distribution with mean 0 and st.dev. 1
y <- matrix(rnorm(n*p), nrow=p, ncol=n,
            dimnames=list(paste("g", 1:p, sep="") , paste("s", 1:n, sep=")))

## genes in set1 are expressed at higher levels in the last 10 samples
y[geneSets$set1, (nGrp1+1):n] <- y[geneSets$set1, (nGrp1+1):n] + 2

## build design matrix
design <- cbind(sampleGroup1=1, sampleGroup2vs1=c(rep(0, nGrp1), rep(1, nGrp2)))

## fit linear model
fit <- lmFit(y, design)

## estimate moderated t-statistics
fit <- eBayes(fit)

## genes in set1 are differentially expressed
topTable(fit, coef="sampleGroup2vs1")

## estimate GSVA enrichment scores for the three sets
gsva_es <- gsva(y, geneSets, mx.diff=1)$es.obs

## fit the same linear model now to the GSVA enrichment scores
fit <- lmFit(gsva_es, design)

## estimate moderated t-statistics
```

```
fit <- eBayes(fit)

## set1 is differentially expressed
topTable(fit, coef="sampleGroup2vs1")
```
