Package 'ClustIRR'

March 9, 2025

Type Package

Title Clustering of immune receptor repertoires

Version 1.5.42

Description ClustIRR analyzes repertoires of B- and T-cell receptors. It starts by identifying communities of immune receptors with similar specificities, based on the sequences of their complementarity-determining regions (CDRs). Next, it employs a Bayesian probabilistic models to quantify differential community occupancy (DCO) between repertoires, allowing the identification of expanding or contracting communities in response to e.g. infection or cancer treatment.

Description

BLOSUM62

Predefined scoring matrix for amino acid or nucleoitide alignments.

BLOSUM62 matrix

Usage

```
data("BLOSUM62")
```

cluster_irr 3

Format

BLOSUM62 is a square symmetric matrix. Rows and columns are identical single letters, representing nucleotide or amino acid. Elements are integer coefficients (substitution scores).

Details

BLOSUM62 was obtained from NCBI (the same matrix used by the stand- alone BLAST software).

Source

See https://ftp.ncbi.nih.gov/blast/matrices/BLOSUM62

References

```

cluster_irr

Clustering of immune receptor repertoires (IRRs)

Description

cluster_irr computes similarities between immune receptors (IRs = T-cell and B-cell receptors) based on their CDR3 sequences.

Usage

Arguments

s

a data.frame with complementarity determining region 3 (CDR3) amino acid sequences observed in IRR clones (data.frame rows). The data.frame has the following columns (IR clone features):

- sample: name of the IRR (e.g. 'A')
- clone_size: cell count in the clone (=clonal expansion)

4 cluster_irr

- CDR3?: amino acid CDR3 sequence. Replace '?' with the appropriate name of the immmune receptor chain (e.g. CDR3a for CDR3s from $TCR\alpha$ chain; or CDR3d for CDR3s from $TCR\delta$ chain. Meanwhile, if paired CDR3s from both chains are available, then you can provide both in separate columns e.g.:
 - *CDR3b* and *CDR3a* [for $\alpha\beta$ TCRs]
 - *CDR3g* and *CDR3d* [for $\gamma \delta$ TCRs]
 - CDR3h and CDR3l [for heavy/light chain BCRs]

meta

data.frame with meta-data for each clone, which may contain clone-specific data, such as, V/J genes, cell-type (e.g. CD8+, CD4+), nut also repertoire-specific data, such as, biological condition, HLA type, age, etc. This data will be used to annotate the graph nodes and help downstream analyses.

control

auxiliary parameters to control the algorithm's behavior. See the details below:

- gmi: the minimum sequence identity between a pair of CDR3 sequences for them to even be considered for alignment and scoring (default = 0.7; 70 percent identity).
- trim_flank_aa: how many amino acids should be trimmed from the flanks of all CDR3 sequences to isolate the **CDR3 cores**. trim_flank_aa = 3 (default).
- db_custom: additional database (data.frame) which allows us to annotate CDR3 sequences from the input (s) with their cognate antigens. The structure of db_custom must be identical to that in data(vdjdb, package = "ClustIRR"). ClustIRR will use the internal databases if db_custom=NULL (default). Three databases (data only from human CDR3) are integrated in ClustIRR: VDJdb, TCR3d and McPAS-TCR.
- db_dist: we compute edit distances between CDR3 sequences from s and from a database (e.g. VDJdb). If a particular distance is smaller than or equal to db_dist (default = 0), then we annotate the CDR3 from s with the specificity of the database CDR3 sequence.

Details

ClustIRR performs the following steps.

- 1. Compute similarities between clones within each repertoire → the function cluster_irr performs this step
- 2. Construct a graph from each TCR repertoire
- 3. Construct a joint similarity graph (J)
- 4. Detect communities in J
- 5. Analyze Differential Community Occupancy (DCO)
 - Between individual TCR repertoires with model M
 - ullet Between groups of TCR repertoires from biological conditions with model M_h
- 6. Inspect results

clust_irr-class 5

Value

The output is an S4 object of class clust_irr. This object contains two sublists:

• clust, list, contains clustering results for each receptor chain. The results are stored as data.frame in separate sub-list named appropriately (e.g. CDR3a, CDR3b, CDR3g, etc.). Each row in the data.frames contains a pair of CDR3s.

The remaining columns contain similarity scores for the complete CDR3 sequences (column weight) or their cores (column cweight). The columns max_len and max_clen store the length of the longer CDR3 sequence and core in the pair, and these used to normalize the scores weight and cweight: the normalized scores are shown in the columns nweight and noweight

• inputs, list, contains all user provided inputs (see Arguments)

Examples

```
# load package input data
data("CDR3ab", package = "ClustIRR")
s <- data.frame(CDR3b = CDR3ab[1:100, "CDR3b"], sample = "A", clone_size = 1)
# run analysis
c <- cluster_irr(s = s)
# output class
class(c)
# output structure
str(c)
# inspect which CDR3bs are similar
knitr::kable(head(slot(c, "clust")$CDR3b))</pre>
```

clust_irr-class

clust irr class

Description

Objects of the class clust_irr are generated by the function cluster_irr. These objects are used to store the clustering results in a structured way, such that they may be used as inputs of other ClustIRR functions (e.g. get_graph, plot_graph, etc.).

The output is an S4 object of class clust_irr. This object contains two sublists:

• clust, list, contains clustering results for each IR chain. The results are stored as data.frame in separate sub-list named appropriately (e.g. CDR3a, CDR3b, CDR3g, etc.). Each row in the data.frames contains a pair of CDR3s.

The remaining columns contain similarity scores for the complete CDR3 sequences (column weight) or their cores (column cweight). The columns max_len and max_clen store the length of the longer CDR3 and CDR3 core sequence in the pair, and these used to normalize the scores weight and cweight: the normalized scores are shown in the columns nweight and ncweight

6 clust_irr-class

• inputs, list, contains all user provided inputs (see Arguments)

Arguments

clust list, contains clustering results for each TCR/BCR chain. The results are stored

in separate sub-list named appropriately (e.g. CDR3a, CDR3b, CDR3g, etc.)

inputs list, contains all user provided inputs

Value

The output is an S4 object of class clust_irr

Accessors

To access the slots of clust_irr object we have two accessor functions. In the description below, x is a clust_irr object.

```
get_clustirr_clust get_clustirr_clust(x): Extract the clustering results (slot clust)
get_clustirr_inputs get_clustirr_inputs(x): Extract the processed inputs (slot inputs)
```

```
# load package input data
data("CDR3ab", package = "ClustIRR")
s <- data.frame(CDR3b = CDR3ab[1:100, "CDR3b"], sample = "A", clone_size = 1)
# run analysis
c <- cluster_irr(s = s)</pre>
# output class
class(c)
# output structure
str(c)
# inspect which CDR3bs are globally similar
knitr::kable(head(slot(c, "clust")$CDR3b))
# clust_irr S4 object generated 'manually' from the individual results
new_clust_irr <- new("clust_irr",</pre>
                     clust = slot(object = c, name = "clust"),
                     inputs = slot(object = c, name = "inputs"))
# we should get identical outputs
identical(x = new_clust_irr, y = c)
```

Datasets 7

Datasets

Datasets CDR3ab and D1 with $TCR\alpha\beta$ mock repertoires

Description

 $TCR\alpha\beta$ repertoire with 10,000 T-cells (rows). Each T-cell has the following features: amino acid sequences of their complementarity determining region 3 (CDR3); and variable (V) and joining (J) gene names for TCR chains α and β .

Important remark: this is a mock dataset, all CDR3 sequences and the genes were sampled from a larger set of CDR3 β sequences and genes of naive CD8+ T cells in humans.

We used this data to create dataset D1: three $TCR\alpha\beta$ repertoires a, b, and c, each with 500 TCR clones. We simulated clonal expansion with increasing degree in TCR repertoires b and c. The TCR repertoires as stores as element of a list. For each TCR repertoires we have a metadata: ma, mb, and mc.

Usage

```
# For the raw data with 10,000 TCR clones
data(CDR3ab)
# For dataset D1
data(D1)
```

Format

data.frame with rows as TCR clones and 6 columns

- CDR3a: CDR3lpha amino acid sequence
- TRAV: variable (V) gene of $TCR\alpha$
- TRAV: joining (J) gene of $TCR\alpha$
- CDR3b: CDR3 β amino acid sequence
- TRBV: variable (V) gene of $TCR\beta$
- TRBV: joining (J) gene of $TCR\beta$

Value

data(CDR3ab) loads the object CDR3ab, which is a data.frame with six columns (3 for $TCR\alpha$ and 3 for $TCR\beta$) and rows for each TCR clone (see details).

data("D1")
```

8 dco

dco

Model-based differential community occupancy (DCO) analysis

Description

This algorithm takes as input a community matrix, and quantifies the relative enrichment/depletion of individual communities in each sample using a Bayesian hierarchical model.

Usage

```
dco(community_occupancy_matrix, mcmc_control, compute_delta=TRUE, groups = NA)
```

Arguments

community_occupancy_matrix

matrix, rows are communities, columns are repertoires, matrix entries are numbers of cells in each community and repertoire.

mcmc_control list, configurations for the Markov Chain Monte Carlo (MCMC) simulation.

- mcmc_warmup = 750; number of MCMC warmups
- mcmc iter = 1500; number of MCMC iterations
- mcmc_chains = 4; number of MCMC chains
- mcmc_cores = 1; number of computer cores
- mcmc_algorithm = "NUTS"; which MCMC algorithm to use
- adapt_delta = 0.95; MCMC step size
- max_treedepth = 12; the max value, in exponents of 2, of what the binary tree size in NUTS should have.

compute_delta should delta be computed by the Stan model? This may be take up extra memory.

groups

vector with integers ≥ 1, one for each repertoire (column in community_occupancy_matrix). This specifies the biological group of each repertoire (e.g. for cancer repertoire we may specify the index 1, and for normal repertoires the index 2). If this vector is specified, ClustIRR will employ a hierarchical model, modeling the dependence between the repertoires within each group. Else (which is the default setting in ClustIRR), ClustIRR will treat the repertoires as independent samples by employing a simpler model.

Value

The output is a list with the folling elements:

fit model fit (stan object)

dco 9

posterior_summary

nested list with data.frames, summary of model parameters, including their means, medians, 95% credible intervals, etc. Predicted observations (y_hat), which are useful for posterior predictive checks are also provided.

community_occupancy_matrix

matrix, rows are communities, columns are repertoires, matrix entries are numbers of cells in each community and repertoire.

mcmc_control mcmc configuration inputs provided as list.

compute_delta the input compute_delta.

groups the input groups.

```
# load package input data
data("CDR3ab", package = "ClustIRR")
a <- data.frame(CDR3a = CDR3ab[1:500, "CDR3a"],</pre>

names(dco)</pre>
```

decode_communities

Decode graph communities

Description

Given a graph based on which we have detected communities (with the function detect_communities), and a community ID, the function will try to partition the community nodes according to user-defined filters: edge and node filters.

For instance, the user may only be interested in retaining edges with core edge weight > 4; or making sure that nodes that have same 'cell_type' (node meta datafrom) are grouped together. Or the user might want to treat all nodes that have the same V, D and J gene names and HLA types as subgroups, in which case all edges between nodes that do not share the same sets of attributes are dicarded.

Based on these filters, ClustIRR will reform the edges in the selected community and then find **connected components** in the resulting graph.

Usage

```
decode_communities(community_id, graph, edge_filter, node_filter)
```

Arguments

graph igraph object that has been analyzed by graph-based community detection meth-

ods as implemented in detect_communities

community_id which community should be decoded?

edge_filter data.frame with edge filters. The deta.frame has three columns:

- name: edge attribute name
- value: edge attribute value (threshold)
- operation: logical operation that tells ClustIRR which edge attribute values should pass the filter. Possible operations: "<", ">=", "<=", "==" and "!=".

node_filter a vector with node attributes. Groups of nodes that have the same attribute values among **ALL** provided attributes will be treated as a subcomponent.

Value

The output is a "filtered" igraph object.

decode_communities 11

```
# load package input data
data("CDR3ab", package = "ClustIRR")
a <- data.frame(CDR3a = CDR3ab[1:300, "CDR3a"],</pre>
                CDR3b = CDR3ab[1:300, "CDR3b"],
                clone\_size = 1,
                sample = "a")
b <- data.frame(CDR3a = CDR3ab[201:400, "CDR3a"],</pre>
                CDR3b = CDR3ab[201:400, "CDR3b"],
                clone_size = 1,
                sample = "b")
b$clone_size[1] <- 20
# run ClustIRR analysis
c <- c(cluster_irr(s = a), cluster_irr(s = b))</pre>
# get joint graph
jg <- get_joint_graph(clust_irrs = c)</pre>
# detect communities
gcd <- detect_communities(graph = jg$graph,</pre>
                           weight = "nweight",
                           algorithm = "leiden",
                           resolution = 1,
                           iterations = 100,
                           chains = c("CDR3a", "CDR3b"))
# We "decompose" the communities in the gcd object using decode_community
# based on the attributes of the edges (edge_filter) and nodes (node_filter).
# We can pick from these edge attributes and create filters:
library(igraph)
edge_attr_names(graph = gcd$graph)
# For instance, the following edge-filter will instruct ClustIRR to keep
# edges with: edge attributes: nweight>=3 \bold{AND} ncweight>=3
edge_filter <- rbind(data.frame(name = "nweight", value = 3, operation = ">="),
                     data.frame(name = "ncweight", value = 3, operation = ">="))
# In addition, we can construct filters based on the following node attributes:
vertex_attr_names(graph = gcd$graph)
# The following node-filter will instruct ClustIRR to retain edges
# between nodes that have shared node attributed with respect to ALL
# of the following node attributes:
node_filter <- data.frame(name = "Ag_gene")</pre>
# Lets inspect community with ID = 1.
c1 <- decode_communities(community_id = 1,</pre>
                         graph = gcd$graph,
                          edge_filter = edge_filter,
```

12 detect_communities

detect_communities

Graph-based community detection (GCD)

Description

Graph-based community detection in graphs constructed by get_graph or get_joint_graph.

Usage

Arguments

graph igraph object

algorithm graph-based community detection (GCD) method: leiden (default), louvain or infomap.

resolution clustering resolution (default = 1) for GCD.

iterations clustering iterations (default = 100) for GCD.

weight which edge weight attribute (default = nweight) should be used for GCD

which chains should be used for clustering? For instance: chains = "CDR3a"; or chains = "CDR3b"; or chains = c("CDR3b", "CDR3b").

Details

ClustIRR employs graph-based community detection (GCD) algorithms, such as Louvain, Leiden or InfoMap, to identify communities of nodes that have high density of edges among each other, and low density of edges with nodes outside the community.

detect_communities 13

Value

The output is a list with the folling elements:

community_occupancy_matrix

matrix, rows are communities, columns are repertoires, matrix entries are numbers of cells in each community and repertoire.

community_summary

data.frame, rows are communities and their properties are provided as columns.

node_summary data.frame, rows are nodes (clones) and their properties are provided as column-

scontains all user provided.

graph igraph object, processed graph object.

graph_structure_quality

graph modularity and quality (only for Leiden) measure of the strength of division of the graph into communities.

input_config list, inputs provided as list.

```
# load package input data
data("CDR3ab", package = "ClustIRR")
a <- data.frame(CDR3a = CDR3ab[1:300, "CDR3a"],</pre>
                   CDR3b = CDR3ab[1:300, "CDR3b"],
                   clone_size = 1,
                   sample = "a")
b <- data.frame(CDR3a = CDR3ab[201:400, "CDR3a"],</pre>
                   CDR3b = CDR3ab[201:400, "CDR3b"],
                   clone\_size = 1,
                   sample = "b")
b$clone_size[1] <- 20
# run ClustIRR analysis
c <- c(cluster_irr(s = a), cluster_irr(s = b))</pre>
# get joint graph
jg <- get_joint_graph(clust_irrs = c)</pre>
# detect communities
gcd <- detect_communities(graph = jg$graph,</pre>
                           weight = "nweight",
                           algorithm = "leiden",
                           resolution = 1,
                           iterations = 100,
                            chains = c("CDR3a", "CDR3b"))
# look at outputs
names(gcd)
# look at the community occupancymatrix
head(gcd$community_occupancy_matrix)
```

14 get_ag_summary

```
# look at the community summary
head(gcd$community_summary$wide)
# look at the node summary
head(gcd$node_summary)
```

get_ag_summary

Estimate the number of antigen-specific T-cells in selected communities

Description

Use node_summary data.frame generated by the function detect_communities; and 2. antigen species/genes to estimate the number of antigen-specific T-cells in selected communities in each repertoire.

Usage

Arguments

node_summary node_summary data.frame

ag_species antigen species, character vector, e.g. c("EBV", "CMV")

ag_genes antigen genes, character vector, e.g. "MLANA"

db annotation database, character, e.g. "vdjdb"

db_dist maximum edit distance threshold for matching, nummeric immune receptor chain for annotation, "both", "CDR3a" or "CDR3b"

Details

The user has to provide a vector of antigen species (e.g. $ag_species = c("EBV", "CMV"))$ and/or a vector of antigen genes (e.g. $ag_genes = "MLANA")$). Furthermore, the user has to provide nodes (node_summary data.frame created by the function detect_communities) and a vector with community IDs.

The user can also select an annotation database db, such as "vdjdb", "mcpas" or "tcr3d"; and restrict the annotation to specific IR chains, such as "CDR3a", "CDR3b" or "both". By default, we will look for perfect matches (db_dist=0) between CDR3 sequences in the input and in the annotation database for annotation. Flexible annotation based on edit distances can be performed by increasing db_dist.

get_beta_scatterplot 15

Value

The output is a data.frame with the number of T-cells specific for the antigenic species/genes (columns) provided as input per repertoire (row), including the total number of T-cells in each repertoire.

Examples

```
# load package input data
data("CDR3ab", package = "ClustIRR")
a <- data.frame(CDR3a = CDR3ab[1:500, "CDR3a"],</pre>
                   CDR3b = CDR3ab[1:500, "CDR3b"],
                   clone_size = 1,
                   sample = "a")
b <- data.frame(CDR3a = CDR3ab[401:900, "CDR3a"],</pre>
                   CDR3b = CDR3ab[401:900, "CDR3b"],
                   clone_size = 1,
                   sample = "b")
b$clone_size[1] <- 20
# run ClustIRR analysis
c <- c(cluster_irr(s = a), cluster_irr(s = b))</pre>
# get joint graph
jg <- get_joint_graph(clust_irrs = c)</pre>
# detect communities
gcd <- detect_communities(graph = jg$graph,</pre>
                            algorithm = "leiden",
                            resolution = 1,
                           weight = "nweight",
                            chains = c("CDR3a", "CDR3b"))
# differential community occupancy analysis
dco <- dco(community_occupancy_matrix = gcd$community_occupancy_matrix)</pre>
ag_summary <- get_ag_summary(node_summary = gcd$node_summary,</pre>
                               ag_species = c("EBV", "CMV"),
                               ag_genes = "MLANA",
                               db = "vdjdb",
                               db_dist = 0,
                               chain = "both")
```

get_beta_scatterplot Compare community βs between pairs of repertoires

Description

Visualize the β means as a 2D scatterplot, representing relative community occupancies for all pairs of repertoires. At the same time, annotate the communities (dots) based on their specificity.

16 get_beta_scatterplot

Usage

Arguments

beta	beta data.frame
node_summary	node_summary data.frame
ag_species	antigen species, character vector, e.g. c("EBV", "CMV")
ag_genes	antigen genes, character vector, e.g. "MLANA"
db	annotation database, character, e.g. "vdjdb"
db_dist	maximum edit distance threshold for matching, nummeric
chain	immune receptor chain for annotation, "both", "CDR3a" or "CDR3b"

Details

The user has to provide a vector of antigen species (e.g. $ag_{species} = c("EBV", "CMV"))$ and/or a vector of antigen genes (e.g. $ag_{genes} = "MLANA")$). Furthermore, the user has to provide nodes (node_summary data.frame created by the function detect_communities) and beta data.frame which is part of posterior_summary generated by the function dco.

The user can also select an annotation database db, such as "vdjdb", "mcpas" or "tcr3d"; and restrict the annotation to specific IR chains, such as "CDR3a", "CDR3b" or "both". By default, we will look for perfect matches (db_dist=0) between CDR3 sequences in the input and in the annotation database for annotation. Flexible annotation based on edit distances can be performed by increasing db_dist.

Value

```
The output is a list with 4 elements:
node_annotations: annotated node_summary
beta_summary: annotated beta
vars: annotation variables
```

scatterplots: a list of scatterplots: Each element of the list contains a scatterplots for a specific antigen species/gene. Within each element of the list there are n^2 panels (comparisons between repertoire pairs), with n as the number of repertoires.

get_beta_scatterplot 17

```
# load package input data
data("CDR3ab", package = "ClustIRR")
a <- data.frame(CDR3a = CDR3ab[1:500, "CDR3a"],</pre>
                   CDR3b = CDR3ab[1:500, "CDR3b"],
                   clone_size = 1,
                   sample = "a")
b <- data.frame(CDR3a = CDR3ab[401:900, "CDR3a"],</pre>
                   CDR3b = CDR3ab[401:900, "CDR3b"],
                   clone_size = 1,
                   sample = "b")

                                           chain = "both")
```

18 get_beta_violins

get_beta_violins

Visualize distribution of β means in each repertoire as violin plots

Description

Visualize the β means as violin plots, representing relative community occupancies for individual repertoires. At the same time, annotate the communities (dots) based on their specificity.

Usage

Arguments

beta beta data.frame

node_summary node_summary data.frame

ag_species antigen species, character vector, e.g. c("EBV", "CMV")

ag_genes antigen genes, character vector, e.g. "MLANA"

db annotation database, character, e.g. "vdjdb"

db_dist maximum edit distance threshold for matching, nummeric immune receptor chain for annotation, "both", "CDR3a" or "CDR3b"

Details

The user has to provide a vector of antigen species (e.g. $ag_{species} = c("EBV", "CMV"))$ and/or a vector of antigen genes (e.g. $ag_{genes} = "MLANA")$). Furthermore, the user has to provide nodes (node_summary data.frame created by the function detect_communities) and beta data.frame which is part of posterior_summary generated by the function dco.

The user can also select an annotation database db, such as "vdjdb", "mcpas" or "tcr3d"; and restrict the annotation to specific IR chains, such as "CDR3a", "CDR3b" or "both". By default, we will look for perfect matches (db_dist=0) between CDR3 sequences in the input and in the annotation database for annotation. Flexible annotation based on edit distances can be performed by increasing db_dist.

Value

```
The output is a list with 4 elements: node_annotations: annotated node_summary beta_summary: annotated beta
```

19 get_graph

vars: annotation variables

violins: violin plots (one for each antigen species and gene)

violins: a list of violin plots. Each element of the list contains a violin visual for a specific antigen species/gene.

Examples

get_graph

```
# load package input data
data("CDR3ab", package = "ClustIRR")
a <- data.frame(CDR3a = CDR3ab[1:500, "CDR3a"],
                  CDR3b = CDR3ab[1:500, "CDR3b"],
                   clone_size = 1,
                   sample = "a")
b <- data.frame(CDR3a = CDR3ab[401:900, "CDR3a"],</pre>
                  CDR3b = CDR3ab[401:900, "CDR3b"],
                   clone_size = 1,
                   sample = "b")
b$clone_size[1] <- 20
# run ClustIRR analysis
c <- c(cluster_irr(s = a), cluster_irr(s = b))</pre>
# get joint graph
jg <- get_joint_graph(clust_irrs = c)</pre>
# detect communities
gcd <- detect_communities(graph = jg$graph,</pre>
                           algorithm = "leiden",
                           resolution = 1,
                           weight = "ncweight",
                           chains = c("CDR3a", "CDR3b"))
# differential community occupancy analysis
dco <- dco(community_occupancy_matrix = gcd$community_occupancy_matrix)</pre>
# generate beta violin plots
beta_violins <- get_beta_violins(beta = dco$posterior_summary$beta,</pre>
                                  node_summary = gcd$node_summary,
                                  ag_species = c("EBV", "CMV"),
                                  ag_genes = "MLANA",
                                  db = "vdjdb",
                                  db_dist = 0,
                                  chain = "both")
```

20 get_honeycombs

Description

Given a clust_irr object generated by the function cluster_irr, the function get_graph constructs an igraph object.

The graph nodes represent IR clones. Undirected edges are drawn between pairs of nodes, and the attributes of these edges are assigned based on the clust_irr outputs: $\bar{\omega}$, $\bar{\omega}_c$, etc.

Usage

```
get_graph(clust_irr)
```

Arguments

clust_irr

S4 object generated by the function cluster_irr

Value

The output is a list with the following elements. First, the list contains an igraph object. The graph nodes and edges contain attributes encoded in the clust_irr objects. Second, it contains a data.frame in which rows are clones (nodes) in the graph. Third, the list contains the logical variable joint_graph, which is set to TRUE if the graph is a joint graph generated by the function get_joint_graph and FALSE if the graph is not a joint graph generated by get_graph.

Examples

```
# load package input data
data("CDR3ab", package = "ClustIRR")
s <- data.frame(CDR3b = CDR3ab[1:100, "CDR3b"], sample = "A", clone_size = 1)
# run ClustIRR analysis
out <- cluster_irr(s = s)
# get graph
g <- get_graph(clust_irr = out)
names(g)</pre>
```

get_honeycombs

Generate honycomb plot: visualize community occupancy of pairs of immune receptor repertoires

Description

Use the community_occupancy_matrix generated by the function detect_communities to generate honeycomb plots for each pair of repertoires. In each plot, we will show communities (rows in the matric community_occupancy_matrix) as dots and their intensities in a pair of repertoires (x-axis and y-axis). The density of dots is encoded by the color of the honeycomb-like hexagons.

get_honeycombs 21

Usage

```
get_honeycombs(com)
```

Arguments

com

community_occupancy_matrix, matrix generated by detect_communities

Details

Use the community_occupancy_matrix generated by the function detect_communities to generate honeycomb plots for each pair of repertoires. In each plot, we will show communities (rows in the matric community_occupancy_matrix) as dots and their intensities in a pair of repertoires (x-axis and y-axis). The density of dots is encoded by the color of the honeycomb-like hexagons.

Value

The output is a list with ggplots. Given n repertoires (columns in input community_occupancy_matrix), it will generate n*(n-1)/2 plots. You can arrange the ggplots (or a portion of them) in any shape e.g. with the R-package patchwork.

```
# load package input data
data("CDR3ab", package = "ClustIRR")
a <- data.frame(CDR3a = CDR3ab[1:300, "CDR3a"],</pre>
                 CDR3b = CDR3ab[1:300, "CDR3b"],
                 clone\_size = 1,
                 sample = "a")
b <- data.frame(CDR3a = CDR3ab[201:400, "CDR3a"],</pre>
                   CDR3b = CDR3ab[201:400, "CDR3b"],
                   clone_size = 1,
                   sample = "b")
b$clone_size[1] <- 20
# run ClustIRR analysis
c <- c(cluster_irr(s = a), cluster_irr(s = b))</pre>
# get joint graph
jg <- get_joint_graph(clust_irrs = c)</pre>
# detect communities
gcd <- detect_communities(graph = jg$graph,</pre>
                           algorithm = "leiden",
                           resolution = 1,
                           weight = "ncweight",
                            chains = c("CDR3a", "CDR3b"))
# get honeycombs
g <- get_honeycombs(com = gcd$community_occupancy_matrix)</pre>
```

get_joint_graph

g

Description

Given a vector of clust_irr objects, generated by the function cluster_irr, the function get_joint_graph performs the following steps:

- 1. runs the function get_graph on each clust_irr object
- 2. merges the nodes: if graph a and b have |a| and |b| nodes, then the joint graph has |a|+|b| nodes, regardless of whether exactly the same clone (vertex) is found in both graphs.
- 3. draws edges between nodes from the different graphs using the same algorithm for drawing edges between nodes within an IRR (see function clust_irr).
- 4. return a joint graph as igraph object
- 5. return the input clustirr object list
- 6. return a logical joint_graph=TRUE

Usage

```
get_joint_graph(clust_irrs, cores = 1)
```

Arguments

clust_irrs A list of at least two S4 objects generated with the function cluster_irr cores number of computer cores to use (default = 1)

Value

The main output is an igraph object.

```
# load package input data
data("CDR3ab", package = "ClustIRR")
a <- data.frame(CDR3b = CDR3ab[1:100, "CDR3b"], sample = "a", clone_size = 1)
b <- data.frame(CDR3b = CDR3ab[1:100, "CDR3b"], sample = "b", clone_size = 1)
# run ClustIRR analysis
c <- c(cluster_irr(s = a), cluster_irr(s = b))
# get graph
g <- get_joint_graph(clust_irrs = c)
names(g)</pre>
```

mcpas 23

mcpas

CDR3 sequences and their matching epitopes obtained from McPAS-TCR

Description

data.frame with CDR3a and/or CDR3b sequences and their matching antigenic epitopes obtained from McPAS-TCR. The remaining CDR3 columns are set to NA. For data processing details see the script inst/script/get_mcpastcr.R

Usage

```
data(mcpas)
```

Format

data. frame with columns:

- 1. CDR3a: CDR3a amino acid sequence
- 2. CDR3b: CDR3b amino acid sequence
- 3. CDR3g: CDR3g amino acid sequence -> NA
- 4. CDR3d: CDR3d amino acid sequence -> NA
- 5. CDR3h: CDR3h amino acid sequence -> NA
- 6. CDR31: CDR31 amino acid sequence -> NA
- 7. CDR3_species: CDR3 species (e.g. human, mouse, ...)
- 8. Antigen_species: antigen species
- 9. Antigen_gene: antigen gene
- 10. Reference: Reference (Pubmed ID)

Value

data(mcpas) loads the object McPAS-TCR

Source

```
McPAS-TCR, June 2024
```

```
data(mcpas)
```

plot_graph

plot_graph	Plot ClustIRR graph	

Description

This function visualizes a graph. The main input is g object created by the function get_graph.

Usage

Arguments

	g	Object returned by the functions get_graph or get_joint_graph		
	as_visnet	logical, if as_visnet=TRUE we plot an interactive graph with visNetwork. If as_visnet=FALSE, we plot a static graph with igraph.		
	select_by	character string, two values are possible: "Ag_species" or "Ag_gene". This only has an effect if as_visnet = TRUE, i.e. if the graph is interactive. It will allow the user to highligh clones (nodes) in the graph that are associated with a specific antigenic specie or gene. The mapping between CDR3 and antigens is extracted from databases, such as, VDJdb, McPAS-TCR and TCR3d. This mapping is done by the function get_graph. If none of the clones in the graph are matched to a CDR3, then the user will have no options to select/highlight.		
show_singletons				
		$logical, if \verb show_singletons=TRUE we plot all vertices. If \verb show_singletons=FALSE , we plot only vertices connected by edges.$		
	node_opacity	probability, controls the opacity of node colors. Lower values corresponding to		

Value

The output is an igraph or visNetwork plot.

more transparent colors.

The size of the vertices increases linearly as the logarithm of the degree of the clonal expansion (number of cells per clone) in the corresponding clones.

```
# load package input data
data("CDR3ab", package = "ClustIRR")
s <- data.frame(CDR3b = CDR3ab[1:100, "CDR3b"], sample = "A", clone_size = 1)
# run ClustIRR analysis</pre>
```

tcr3d 25

```
out <- cluster_irr(s = s)
# get graph
g <- get_graph(clust_irr = out)
# plot graph with vertices as clones
plot_graph(g, as_visnet=FALSE, show_singletons=TRUE, node_opacity = 0.8)</pre>
```

tcr3d

CDR3 sequences and their matching epitopes obtained from TCR3d

Description

data.frame with paired CDR3a and CDR3b CDR3 sequences and their matching epitopes obtained from TCR3d. The remaining CDR3 columns are set to NA. The antigenic epitopes come from cancer antigens and from viral antigens. For data processing details see the script inst/script/get_tcr3d.R

Usage

```
data(tcr3d)
```

Format

data.frame with columns:

- 1. CDR3a: CDR3a amino acid sequence
- 2. CDR3b: CDR3b amino acid sequence
- 3. CDR3g: CDR3g amino acid sequence -> NA
- 4. CDR3d: CDR3d amino acid sequence -> NA
- 5. CDR3h: CDR3h amino acid sequence -> NA
- 6. CDR31: CDR31 amino acid sequence -> NA
- 7. CDR3_species: CDR3 species (e.g. human, mouse, ...)
- 8. Antigen_species: antigen species
- 9. Antigen_gene: antigen gene
- 10. Reference: Reference ID

Value

data(tcr3d) loads the object tcr3d

Source

```
TCR3d, June 2024
```

```
data("tcr3d")
```

26 vdjdb

vdjdb

CDR3 sequences and their matching epitopes obtained from VDJdb

Description

data.frame with unpaired CDR3a or CDR3b sequences and their matching epitopes obtained from VDJdb. The remaining CDR3 columns are set to NA. For data processing details see the script inst/script/get_vdjdb.R

Usage

```
data(vdjdb)
```

Format

data.frame with columns:

- 1. CDR3a: CDR3a amino acid sequence
- 2. CDR3b: CDR3b amino acid sequence
- 3. CDR3g: CDR3g amino acid sequence -> NA
- 4. CDR3d: CDR3d amino acid sequence -> NA
- 5. CDR3h: CDR3h amino acid sequence -> NA
- 6. CDR31: CDR31 amino acid sequence -> NA
- 7. CDR3_species: CDR3 species (e.g. human, mouse, ...)
- 8. Antigen_species: antigen species
- 9. Antigen_gene: antigen gene
- 10. Reference: Reference (Pubmed ID)

Value

data(vdjdb) loads the object vdjdb

Source

```
VDJdb, December 2024
```

```
data("vdjdb")
```
